(57) **ABSTRACT**

A method of capturing student performance can be provided that includes enabling a course creator to generate assessment data related to learning assessments for an online course and to generate learning outcomes for the online course, associating the assessment data with the learning outcomes, such that at least some of the learning assessments correspond to at least some of the learning outcomes, and generating an online classroom. The method may further include providing the learning assessments to students enrolled in the online course using the online classroom, wherein the students can generate completed learning assessments, and determining, for each of the completed learning assessments, whether one or more of the learning outcomes were met by each of the students.

RELATED APPLICATIONS

This application is a continuation-in-part of U.S. application Ser. No. 13/688,049, filed Nov. 28, 2012, which is a continuation of U.S. application Ser. No. 12/137,466, filed Jun. 11, 2008, now U.S. Pat. No. 8,326,211, which claims priority from U.S. Provisional Application No. 60/943,286 filed Jun. 11, 2007, entitled "Performance Capture In Online Learning Environments," and from U.S. Provisional Application No. 60/943,267 filed Jun. 11, 2007, entitled "Accreditation-based course creation tools." This application is also a continuation-in-part of U.S. application Ser. No. 13/613,764, filed Sep. 13, 2012, which is a continuation of U.S. application Ser. No. 12/137,418, filed Jun. 11, 2008, which claims priority from U.S. Provisional Application No. 60/943,284, filed Jun. 11, 2007, titled "Online Learning Using an Application Service Provider Model." Each of the foregoing applications is hereby incorporated by reference in its entirety.

BACKGROUND

The Internet has provided educators with an efficient medium for delivering educational materials to a diverse, geographically remote audience. For example, many universities provide educational content to students via the Internet. Even some businesses offer continuing education and training to employees online. Online classes might include presentations of video lectures, written lecture notes, and the like.

Student performance in classes, including online classes, is often measured by grades. Grades can include letters, numbers, or other symbols indicating the relative quality of a student's work. Students receive grades based on their performance on various assessments, such as tests, quizzes, papers, and the like. Grades alone, however, provide only an approximate measure of student performance.

SUMMARY OF CERTAIN EMBODIMENTS

In various embodiments, a computer-implemented method of capturing student performance can be provided that includes enabling a course creator to generate assessment data related to learning assessments for an online course and to generate learning outcomes for the online course, associating the assessment data with the learning outcomes, such that at least some of the learning assessments correspond to at least some of the learning outcomes, and generating an online classroom. The method may further include providing the learning assessments to students enrolled in the online course using the online classroom, wherein the students generate completed learning assessments, and determining, for each of the completed learning assessments, whether one or more of the learning outcomes were met by each of the students.

Additionally, in certain embodiments, a system for measuring student performance can include a course creation module that can enable a course creator to generate learning outcomes for an online course and associate learning assessments with the learning outcomes, such that at least some of the learning assessments correspond to at least some of the learning outcomes. The system may further include an online classroom module that can generate an online classroom and provide the learning assessments to students enrolled in the online course using the online classroom, wherein the students can generate completed learning assessments. In addition,

2

the system may also include a performance capture module that determines, for each of the completed learning assessments, whether one or more of the learning outcomes were met by each of the students.

In certain embodiments, a system for capturing student performance in an online educational course includes a course creation module accessible by a creator of an online educational course. The course creation module can enable the course creator to generate learning assessments for the online course and learning outcomes. The learning outcomes can include course outcomes that each have a desired objective for students to achieve in the online course and lesson outcomes that each have a desired objective for the students to achieve from one or more lessons. Each of the lesson outcomes can be related hierarchically to at least one of the course outcomes. The course creation module can also enable the course creator to associate at least some of the learning assessments with the learning outcomes, such that the at least some of the learning assessments correspond to at least one of the lesson outcomes.

Additionally, the system may further include an online classroom module that generates an online classroom, provides the learning assessments to the students in the online classroom, and automatically grades at least some of the learning assessments to produce graded learning assessments. Moreover the system may also include a performance capture module that determines, for each of the graded learning assessments, whether one or more of the learning outcomes were met.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates a block diagram of an embodiment of an online learning system;

FIG. 2 illustrates a block diagram of another embodiment of the online learning system of FIG. 1;

FIG. 3 illustrates a block diagram of an embodiment of learning outcomes that may be used with the online learning system of FIG. 1 or 2;

FIG. 4 illustrates a flow chart diagram of an embodiment of a process for capturing student performance;

FIG. 5 illustrates a flow chart diagram of another embodiment of a process for capturing student performance;

FIG. 6 illustrates an example user interface for creating an online course based on learning outcomes; and

FIG. 7 illustrates an example report on student performance based on learning outcomes.

FIG. 8 illustrates a block diagram of an embodiment of an online learning system;

FIG. 9 illustrates a block diagram of another embodiment of the online learning system of FIG. 8;

FIG. 10 illustrates a flow chart diagram of an embodiment of a process for provisioning instruction groups using the online learning system of FIG. 8 or 9;

FIG. 11 illustrates a flow chart diagram of an embodiment of a process for authenticating users of instruction groups using the online learning system of FIG. 8 or 9;

FIG. 12 illustrates a block diagram of an embodiment of a database of the online learning system of FIG. 8 or 9; and

FIG. 13 illustrates a block diagram of an embodiment of a file system of the online learning system of FIG. 8 or 9.

DETAILED DESCRIPTION OF CERTAIN EMBODIMENTS

Performance Capture Embodiments

Grades are used ubiquitously in education to provide approximate indicators of student performance. However,

grades provide a one-dimensional view of student accomplishment. Grades themselves, for instance, tell how well students have performed relative to their peers but tell little about what students have learned. Likewise, grades fail to provide significant insights on how well a teacher has conveyed a subject to students.

Various embodiments herein describe enhanced systems and methods for capturing student performance. In certain embodiments, these systems and methods enable courses to be created based on desired learning outcomes. These learning outcomes may be associated with assessments. Student achievement of the learning outcomes may be measured based on their performance on the assessments. Likewise, teacher effectiveness may be gauged based on the students' learning outcome achievements.

Although the systems and methods described herein are described primarily in the context of online classes, these systems and methods may also be used with classes that are not conducted online. In addition, the systems and methods herein are not restricted to classes conducted by schools, but may also be used in corporate training, certificate programs, and other educational settings.

The features of these systems and methods will now be described with reference to the drawings summarized above. Throughout the drawings, reference numbers may be re-used to indicate correspondence between referenced elements. The drawings, associated descriptions, and specific implementation are provided to illustrate embodiments of the inventions described herein and not to limit the scope thereof.

In addition, methods and processes described herein are not limited to any particular sequence, and the blocks or states relating thereto can be performed in other sequences that are appropriate. For example, described blocks or states may be performed in an order other than that specifically disclosed, or multiple blocks or states may be combined in a single block or state. Moreover, the various modules of the systems described herein can be implemented as software applications, hardware and/or software modules, or components on one or more computers, such as servers. While the various modules are illustrated separately, they may share some or all of the same underlying logic or code.

FIG. 1 illustrates an embodiment of an online learning system **100**. The depicted embodiment of the online learning system **100** includes software components that can be implemented using one or more computer systems, such as servers (not shown). In certain embodiments, the online learning system **100** enables teachers and/or administrators to create courses according to desired learning outcomes. Advantageously, in certain embodiments the online learning system **100** captures student progress toward reaching the learning outcomes.

The online learning system **100** may be accessed by users such as students, teachers, and/or administrators over a communications medium **120** such as the Internet, a local or wide area network (LAN or WAN), or the like. The users can access the online learning system **100** using computer systems **110**, **112**. The computer systems **110**, **112** can be any processor-based systems, such as desktops, laptops, tablet computers, personal digital assistants (PDAs), smart phones, ultra-portable computers, and the like. Students may access the online learning system **100** using the computer systems **110** to enroll in courses, receive instruction in interactive online classes, complete assessments, and the like. Teachers may access the online learning system **100** using the computer systems **112** to provide instruction to students, to create and manage courses, and the like. Administrators may also be able to access the online learning system **100** using the computer

systems **114** to create courses, supervise instruction, and perform other administrative tasks.

In the depicted embodiment, the online learning system **100** includes a learning module **130**, a database **140**, and a file system **150**. The learning module **130** can include one or more software components. In one embodiment, the learning module **130** is a software application server that provides access to applications, data, and the like.

In certain embodiments, the learning module **130** provides an online classroom in which students can receive instruction and take assessments. The online classroom may include one or more user interfaces for students, teachers, and administrators to access educational content on the file system **150** and/or in the database **140**. The educational content can include, for example, multimedia presentations, lecture material, course files, and the like. The online classroom can also access student, teacher, and administrator personal data stored in the database **140** and/or file system **150**. The user interfaces can be accessed by web browsers installed on the student, teacher, and administrator computer systems **110**, **112**, **114**. Alternatively, an application other than a web browser can be used to access the online classroom.

The learning module **130** can also enable course creators such as teachers or administrators to create online courses based on one or more desired learning outcomes. The desired learning outcomes can be objectives that course creators desire the students to achieve for a given course. Course creators may generate the learning outcomes based on accreditation requirements in some embodiments. Accreditation requirements can include standards or desired competencies for courses defined by accreditation entities, such as the Accreditation Board for Engineering and Technology (ABET). For example, each accreditation requirement for a given course can be used as a learning outcome for that course. Alternatively, course creators may generate the learning outcomes based on the course creators' own criteria for student accomplishment. Course creators may also generate learning outcomes based on a combination of accreditation requirements and the course creators' own criteria.

Course creators can use the learning module **130** to associate the learning outcomes with assessments. Example assessments can include tests, exams, quizzes, essays, papers, projects, labs, presentations, oral reports, homework, research, class attendance, class participation, combinations of the same, and the like. An assessment associated with a learning outcome may test a student's mastery of the learning outcome. As an example, one possible learning outcome in an English class might be that students learn to recognize different sentence structures. An assessment associated with this learning outcome might test students on the different sentence structures.

The learning module **130** can measure students' learning outcome performance based at least in part on the students' performance on their assessments. For example, if a student performed well on an assessment such as a test, the learning module **130** may consider the student to have achieved a learning outcome associated with that test. The learning module **130** may store learning outcome results of students in the database **140**, generate learning outcome reports for teachers and administrators, and recommend tutoring or other help to students who are not meeting learning outcomes. Using the learning outcome reports, teachers can also identify which students might need additional help. Teachers can also use the learning outcome reports self-diagnostically. If learning outcomes were missed by a number of students, for instance, teachers can identify areas where they may wish to adjust

5

their teaching. Moreover, administrators can analyze learning outcome reports to supervise teachers.

FIG. 2 illustrates another embodiment of an online learning system 200. The depicted embodiment of the online learning system 200 includes software components that can be implemented using one or more computer systems, such as servers (not shown). The online learning system 200 includes a learning module 230, a database 240, and a file system 250. These components may have some or all of the same functionality described above with respect to FIG. 1, as well as additional functionality described below. In certain embodiments, the online learning system 200 advantageously enables teachers and administrators to define learning outcomes for capturing student performance.

The learning module 230 in the depicted embodiment includes a course creation module 232, an online classroom module 234, and a performance capture model 236. The learning module 230 may include more or fewer components in other embodiments.

The course creation module 232 can be a software component for creating courses, such as online courses. The course creation module 232 may be used by course creators such as teachers and administrators to create the online courses. When creating the online courses, course creators can use the course creation module 232 to define, import, or otherwise create learning outcomes. For instance, the course creation module 232 can allow course creators to import learning outcomes and assessments from previously-generated courses, which may be stored in the database 240 or file system 250.

The learning outcomes can be subdivided into different types of learning outcomes. To illustrate, FIG. 3 depicts an embodiment of learning outcomes 300 that are subdivided into course outcomes 304 and lesson outcomes 306. The learning outcomes 300 are arranged hierarchically. For a given course 302, one or more course outcomes 304 may be defined. The course outcomes 304 may be overall objectives for students to achieve by the end of the course 302. Examples of course outcomes 304 for a geometry course 302 might include: "By the end of this course, students should be able to compute the area of common shapes" and "By the end of this course, students should be able to prove common geometric theorems." Two course outcomes 304a, 304b are shown for illustrative purposes; however, any number of course outcomes 304 may be defined for a given course 302.

For one or more of the course outcomes 304, there are one or more lesson outcomes 306 shown. For clarity, lesson outcomes 306 are shown for only the course outcome 304a, although lesson outcomes 306 may also be defined for the course outcome 304b. Each of the lesson outcomes 306 may be narrower in scope than the course outcome 304 with which it is associated. The lesson outcomes 306 can therefore support the course outcomes 304 in certain embodiments. Example lesson outcomes 306 might include: "By the end of this lesson, students should be able to compute the area of triangles" and "By the end of this lesson, students should be able to compute the area of parallelograms."

Each of the lesson outcomes 306 may be further associated with one or more assessments 308. The assessments 308 can be given to students to measure their progress toward completing the lesson outcomes 306, which can in turn show the progress of students toward completing the course outcomes 304. For example, a quiz on "computing the area of parallelograms" could be provided as an assessment 308 that supports the lesson outcome 306 of "By the end of this lesson, students should be able to compute the area of parallelograms." Thus, by measuring students' performance on the assessments 308,

6

the students' performance toward completing the learning outcomes 300 can be captured.

While the assessments 308 are depicted as each relating to one lesson outcome 306, the assessments 308 may also relate to multiple lesson outcomes 306 and/or course outcomes 304. For example, after three lessons have been taught, an assessment 308 such as a test that covers the learning outcomes 306 from all three lessons might be given to students. Likewise, lesson outcomes 306 can be associated with multiple course outcomes 304. Additionally, the assessments 308 may be taken outside of a lesson or class. Moreover, some course outcomes 304 may not be associated with any lesson outcomes 306. The hierarchy of learning outcomes 300 shown may also have fewer or more levels.

Referring again to FIG. 2, once course creators have created learning outcomes, they may use the course creation module 232 to develop lessons that support those learning outcomes. The learning outcomes can therefore be a blueprint for developing a course in some implementations. Course creators may also use the course creation module 232 to generate assessments to gauge student progress in achieving the learning outcomes. The course creation module 232 may store the assessments, data on correct answers for the assessments (where applicable), corresponding grade values for the assessments (where applicable), and the like as assessment data 244 in the database 240.

Course creators can use the course creation module 232 to associate some or all of the learning outcomes with assessments and to store the associations in one or more assessment-outcomes tables 242 in the database 240. The course creation module 232 can also allow course creators to create criteria for determining whether learning outcomes have been met. These criteria can also be stored in the assessment-outcomes tables 242.

One example of such criteria is grade thresholds. For some assessments, course creators can define grade thresholds that indicate a minimum (or maximum) grade that satisfies a given learning outcome. For example, a grade of 75 out of 100 might be used as a threshold grade, such that students receiving a 75 or above will be considered to have achieved a learning outcome. The threshold may be in the form of a percentage, a raw number, a letter grade, or the like. The threshold may also be as simple as a "Pass" grade on a pass/fail assessment.

Grade thresholds may also be used for portions of assessments. For example, teachers may give multiple grades to an assessment. An English paper, for instance, might be assigned one grade for content and another grade for grammar. Each grade of multi-grade assessments may have a threshold that corresponds to different learning outcomes. The thresholds can be the same or different. Referring again to the English paper example, the content grade might be given a threshold of "75" (on a 0-100 scale), whereas the grammar grade might be given a threshold of "85."

Another example criteria for determining achievement of learning outcomes is based on questions of assessments, rather than (or possibly in addition to) grades. For instance, individual questions within an assessment may be assigned to one or more learning outcomes. Questions 1-3 on a test, for example, might relate to one learning outcome, while questions 4-10 relate to another learning outcome. Thus, answering a certain question, number of questions, percentage of questions, or subparts of questions correctly can demonstrate achievement of one or more learning outcomes. In addition, one question or set of questions can correspond to multiple learning outcomes.

The course creation module **232** can allow course creators to weight assessments or portions thereof. For example, one assessment might be given a higher weight than another assessment in determining whether learning outcomes have been met. Similarly, subparts of assessments, such as questions, can be assigned different weights in determining whether learning outcomes have been met. Moreover, one subpart of an assessment (e.g., a question), can have multiple weightings for different outcomes. For example, one question might be related 25% to one lesson outcome and 75% to another lesson outcome.

Other example criteria that can be defined for achieving learning outcomes include the percentage of completion of an assessment (e.g., the percentage of classes attended by students). In addition, when the learning outcomes include both lesson and course outcomes, the criteria for achievement of a course outcome can be based on the number lesson outcomes achieved, the percentage of lesson outcomes achieved, or the like. Many other criteria may be defined for determining learning outcome achievement in various embodiments.

In certain embodiments, the online classroom module **234** generates the online classroom described above with respect to FIG. 1. The online classroom can be used by teachers to provide classroom instruction. In addition, the online classroom can include interfaces for giving assessments to students. The online classroom module **234** can store completed assessments in the assessment data **244**. In addition, in some implementations, the online classroom module **234** can automatically grade at least some of the assessments. For example, the online classroom module **234** can access an answer key or the like stored in the assessment data **244** and compare the students' answers with the answer key. In other embodiments, at least some of the assessments are graded manually by a teacher, teacher's assistant, or the like. Some papers, for instance, might be graded by hand. Teachers can input manually-generated grades into the online learning system **200** using the online classroom module **234**. The online classroom module **234** can store automatically or manually generated grades in the assessment data **244**.

In certain embodiments, the performance capture module **236** can retrieve the completed assessments and other assessment data **244** from the database **240** or directly from the online classroom module **234**. The performance capture module **236** can then analyze the completed assessments according to the criteria described above to determine whether learning outcomes were achieved. For example, the performance capture module **236** can compare the assessment data **244** to the criteria described above, such as grade thresholds or the like, to determine whether learning outcomes have been met. The performance capture module **236** can store its analysis in the database **240**. In addition, the performance capture module **236** can generate reports on student performance and provide these reports to teachers, administrators, students, and the like. One example of a report is described below with respect to FIG. 7. Moreover, the performance capture module **236** can provide these reports to accreditation entities to show evidence of compliance with accreditation standards.

FIG. 4 illustrates an example process **400** for capturing student performance. The process **400** can be performed by any of the online learning systems described above, such as the online learning systems **100** or **200**. In particular, in certain embodiments, the course creation module **232**, online classroom module **234**, and performance capture module **236** described above can perform certain aspects of the process **400**. Advantageously, in certain embodiments, the process **400** enables teachers or administrators to capture student performance.

At block **402**, course and learning outcomes are defined. The course and learning outcomes can be defined using, for example, the course creation module **232**. The course and learning outcomes can indicate objectives to which students should aim to achieve. At block **402**, assessments are generated based on one or more of the outcomes. Each of the assessments can relate to one or more of the outcomes. This block **402** may also be implemented by the course creation module **232**.

At block **406**, the assessments are provided to students. Assessments can be taken by the students online in an interactive classroom using, for example, the online classroom module **234**. At block **408**, the assessments are graded. The assessments may be automatically graded by the performance capture module **236**. Alternatively, the assessments can be hand-graded by a teacher, teacher's assistant, or the like. In the case of hand-graded assessments, the hand grades can be entered into the database **240** using the online classroom module **234** or the like.

At block **410**, the grades are correlated with the outcomes tested to determine student and teacher progress with meeting performance goals. Block **410** may also be performed using the performance capture module **236**. The individual questions may also be correlated with outcomes tested. More generally, any part of an assessment may be correlated with one or more learning outcomes.

FIG. 5 illustrates another embodiment of a process for capturing student performance. Like the process **400**, the process **500** may be implemented by any of the online learning systems described above, such as the online learning systems **100** and **200**. In particular, in certain embodiments, the online classroom module **234** and the performance capture module **236** described above can perform certain aspects of the process **500**. Advantageously, in certain embodiments, the process **500** enables students to receive additional help if they are having difficulty achieving learning outcomes.

At block **502**, assessments are provided to students. The assessments may be provided, for example, by the online classroom module **234**. The remaining blocks **504-510** of the process **500** may be implemented by the performance capture module **236**. At block **504**, the assessments may be graded automatically or by hand. In the case of hand-grading, the grades may be entered into the performance capture module **236**.

At block **506**, it is determined for a given student whether one or more learning outcomes were met. This determination may include, for instance, analyzing assessments to determine if grades exceeded a predetermined threshold. If a student failed to achieve one or more outcomes, at block **508** tutoring can be automatically recommended to the student. Tutoring can be recommended, for example, by the performance capture module **236** sending an electronic message regarding tutoring to the student. The student may be recommended online tutoring for additional review in the subject matter of the one or more learning outcomes the student missed. The online tutoring may be performed in one embodiment using the online tutoring system described in U.S. patent application Ser. No. 12/137,422, filed Jun. 11, 2008, entitled "Computer systems and methods for providing online tutoring," the disclosure of which is hereby incorporated by reference in its entirety. Instead of tutoring, the student may be provided with additional content to review at block **508**. This additional content may include lecture notes, outside reading material, or the like.

At block **510**, it is determined whether to analyze the assessments of other students. If so, then the process loops back to block **506**. Otherwise the process **500** ends.

FIG. 6 illustrates an example course creation display 600 for creating an online course based on learning outcomes. The course creation display 600 may be generated by any of the online learning systems described above, including the online learning systems 100 and 200. In particular, in certain embodiments the course creation display 600 may be generated by the course creation module 232.

The example course creation display 600 is depicted in a web browser 610. In other embodiments, the course creation display 600 can be accessed using an application other than a web browser. The course creation display 600 may be included as part of several displays used to create a course. In certain embodiments, the course creation display 600 enables a course creator, such as a teacher or administrator, to create learning outcomes for a course.

The example course creation display 600 includes user interface controls 602 for selecting a course and user interface controls 604 for defining course outcomes for the selected course. The user interface controls 604 for defining course outcomes include text boxes in the depicted embodiment for entering descriptive text of a course outcome. For each course outcome, there are additional user interface controls 606 for creating lesson outcomes. These user interface controls 606 also include text boxes for entering descriptive text of a lesson outcome.

Similarly, user interface controls 608 may be used to link assessments with lesson and/or course outcomes. The user interface controls 608 include "Browse" buttons in the depicted embodiment for searching for assessment files. Other controls may be provided in certain embodiments for generating assessments from scratch. The assessments shown ("Test1.xml" and "Homework1.xml") are in extensible markup-language (XML) format. The XML format can be used in certain embodiments to facilitate parsing of answers from the assessments. However, many other formats can be used for the assessments in other embodiments.

FIG. 7 illustrates an example report display 700 for a report on student learning outcome performance. The report display 700 may be generated by any of the online learning systems described above, including the online learning systems 100 and 200. In particular, in certain embodiments the performance capture module 236 can generate the report display 700. The report display 700 may be used by a teacher, for example, to evaluate the progress of students in achieving learning outcomes.

The example report display 700 of the online classroom is depicted in a web browser 710. In other embodiments, the report display 700 can be accessed using an application other than a web browser. The report display 700 illustrates a lesson outcome report showing lesson outcome results for several students 708. For each student 708, assessment grades 712 corresponding to the depicted lesson outcome are shown in tabular format. The assessment grades 712 are combined into an average grade 714, which in the depicted embodiment is a weighted average.

Lesson outcome results 716 are also shown for each student. Where the average grade 714 meets or exceeds a threshold (in the depicted example, "85"), the lesson outcome results 714 indicate that the student 708 met the lesson outcome. Otherwise, the lesson outcome results 714 indicate that the student did not meet the lesson outcome.

Application Service Provider Embodiments

The Internet has provided educators with an efficient medium for delivering educational materials to a diverse, geographically remote audience. For example, many educa-

tional institutions provide educational content to students via the Internet. Many businesses and other organizations also offer continuing education and training to employees online. Online classes might include presentations of video lectures, written lecture notes, and the like.

Some educational institutions, businesses, and other organizations employ the hosting services of businesses called application service providers (ASPS). ASPS own or maintain computer systems such as servers that can host software, such as online learning software. Users such as students, teachers, and administrators can access the online learning software over the Internet or another communications medium. For example, the users might use a web browser or the like to access educational web pages or other educational network resources hosted on the ASP computer systems.

Security is a priority for ASPS. ASP security can include physical security, including physically secure facilities requiring, for example, badge or biometric access. In addition, ASPS generally attempt to secure their computer systems against software attacks and the like.

In hosting software for multiple organizations, ASPS may take steps to segregate each organization's programs and data stored on its servers for security and other reasons. ASPS may, for instance, run separate instances of the same program in computer memory for each organization. Likewise, ASPS may maintain separate databases and file systems for each organization. This duplication of running programs and data can be wasteful of computing resources, including processing, memory, and storage resources. In addition, the additional overhead of maintaining separate programs and data can create an administrative burden.

Certain embodiments herein describe systems and methods for providing a plurality of organizations, such as businesses, nonprofit organizations, government organizations, schools, and the like with access to hosted educational programs and data. In certain embodiments, these systems and methods can allow multiple organizations to share the same running instances of programs and share databases and file systems. As a result, in various implementations, computing resources can be conserved.

While the systems and methods herein are described primarily in the context of online learning, the systems and methods herein may be implemented in other contexts. For example, the systems and methods described herein may be implemented in any system having hosted software, such as ASP computer systems.

The features of these systems and methods will now be described with reference to the drawings summarized above. Throughout the drawings, reference numbers may be re-used to indicate correspondence between referenced elements. The drawings, associated descriptions, and specific implementation are provided to illustrate embodiments of the inventions described herein and not to limit the scope thereof.

In addition, methods and processes described herein are not limited to any particular sequence, and the blocks or states relating thereto can be performed in other sequences that are appropriate. For example, described blocks or states may be performed in an order other than that specifically disclosed, or multiple blocks or states may be combined in a single block or state. Moreover, the various modules of the systems described herein can be implemented as software applications, hardware and/or software modules, or components on one or more computers, such as servers. While the various modules are illustrated separately, they may share some or all of the same underlying logic or code.

FIG. 8 illustrates an embodiment of an online learning system 800. The depicted embodiment of the online learning

system **800** includes software components that can be implemented using one or more computer systems, such as servers (not shown). The online learning system **800** can be hosted by an ASP or the like. In certain embodiments, the online learning system **800** enables groups of users, including businesses, nonprofit organizations, government organizations, schools, and the like to access educational programs and data online.

The online learning system **800** may be accessed by users such as students, tutors, teachers, and/or administrators over a communications medium **820** such as the Internet, a local or wide area network (LAN or WAN), or the like. As used herein, the terms “student,” “teacher,” and “administrator,” in addition to having their broad ordinary meaning, can include users who are not affiliated with an educational institution. A student, for example, can be any user who accesses the online tutoring system **800** to receive instruction. Similarly, a teacher or administrator can be any user who accesses the online learning system **800** to provide instruction and/or to perform administrative tasks related to the online learning system **800**.

The users can access the online learning system **800** using computer systems **802**. The computer systems **802** can be any processor-based systems, such as desktops, laptops, tablet computers, personal digital assistants (PDAs), smart phones, ultra-portable computers, and the like. Students may access the online learning system **800** to enroll in courses, receive instruction in online classes, complete homework assignments and projects, take tests and other assessments, and the like. Teachers may access the online learning system **800** to provide instruction to students, to create and manage courses, and the like. Administrators may also be able to access the online learning system **800** to supervise instruction and perform other administrative tasks.

The depicted online learning system **800** includes an application server **830**, a database **840**, and a file system **850**. The application server **830** can be a software component such as a software engine or the like. The application server **830** can communicate with the users of the instruction groups **810** through the communications medium **820**. The application server **830** can provide an online classroom in which students can be taught. The online classroom may include one or more user interfaces for communicating between students, teachers, and other students. The user interfaces can be accessed by web browsers or the like installed on the student and teacher computer systems **802**. Alternatively, an application other than a web browser on the computer systems **802** can be used to access the online classroom provided by the application server **830**.

The application server **830** can store user data **842**, such as user contact information, student grades, class schedules, and the like, in the database **840**. The application server **830** can also store educational content **852** and student and teacher data, including documents, files, and the like, in the file system **850**. In some embodiments, the application server **830** can also store educational content and student and teacher data in the database **840**. Through the online classroom or other user interfaces generated by the application server **830**, students and teachers can access the data and educational content stored in the database **840** and file system **850**.

The application server **830** may group users into instruction groups **810**. Two instruction groups **810a**, **810b** are shown for illustrative purposes, but additional instruction groups **810** may access the online learning system **800**. Entire organizations or parts thereof can be assigned to instruction groups **810**. These organizations can include elementary or secondary schools (e.g., K-12 schools), higher education institutions (such as colleges, vocational schools, and univer-

sities), businesses, non-profit organizations, government organizations (e.g., military and agencies) and the like. Subsets of organizations that may be assigned to instruction groups **810** can include, for example, a group of corporate workers enrolled in a training program, a class of students at a university, and the like. In addition, users from different organizations (or no organization at all) may be assigned to instruction groups **810** in certain embodiments. For instance, users who have a common interest but who may be from different organizations may sign up for an online class and be grouped together as an instruction group **810**. Users can simultaneously be in multiple instruction groups.

In certain embodiments, the instruction groups **810** are created by creating a unique instruction group identifier for each instruction group **810**. The instruction group identifier can be an alphanumeric string or the like. The instruction group identifiers may be kept internal to the online learning system **800**, such that users do not know of the instruction group identifiers' existence or of users' assignment to instruction groups **810**. Instruction group identifiers may be mapped to users, and these mappings may be stored in the database **830**, as is described in greater detail below with respect to FIG. 9.

In certain embodiments, assigning users to instruction groups **810** can allow certain software components of the online learning system **800** to be shared amongst different instruction groups **810**. As a result, computing resources in the online learning system **800** may be used more efficiently and securely in certain implementations. To illustrate, in one embodiment, one running instance of the application server **830** may be shared by multiple instruction groups **810**. This running instance of the application server **830** can run online classrooms and optionally other programs for each of the instruction groups **810**. Similarly, data stored in the database **840** and file system **850** can be associated with the instruction group identifier of each instruction group **810** to facilitate sharing of the database **840** and file system **850**. As will be described in further detail with respect to FIGS. 9 and 12 below, in various embodiments the application server **830**, database **840**, and file system **850** can be shared by providing access to programs and data according to the instruction group identifier for each instruction group **810**.

Because the application server **830**, database **840**, and file system **850** can be shared by multiple instruction groups **810**, in some embodiments these components can be implemented in one server or other computing device. Thus, in certain embodiments, each organization may not need to incur the costs of using a separate server to access educational content. In alternative embodiments, the application server **830**, database **840**, and file system **850** can be distributed over multiple servers, processors, and/or memory devices. Additionally, portions of the online learning system **800** may be loaded onto different processors, memory devices, or servers. For example, the application server **830** may be run on a different server than the database **840**.

In still other embodiments, some components of the online learning system **800** may share resources differently than others. An instance of the application server **830** might be shared, for example, while separate databases **840** or file systems **850** may be maintained for each instruction group **810**. In addition, one application server **830**, database **840**, and file system **850** might be shared amongst a first set of instruction groups **810**, while another application server **830**, database **840**, and file system **850** might be shared by another set of instruction groups **810**. Many other combinations of sharing application servers **830**, databases **840**, and file systems **850** may also be used.

Another advantage of using fewer application servers **830**, databases **840**, and file systems **850** for multiple instruction groups **810** in certain embodiments is that it can be easier to duplicate the entire online learning system **800**. Duplicating the online learning system **800**, or portions thereof, can allow the online learning system **800** to run on multiple servers for load balancing and fault tolerance purposes. In addition, in certain embodiments, the online learning system **800** uses fewer overhead computing resources because the communication between instances of multiple application servers, databases, and file systems is reduced or eliminated.

FIG. 9 illustrates another embodiment of an online learning system **900**. The depicted embodiment of the online learning system **900** includes software components that can be implemented using one or more computer systems, such as servers (not shown). The online learning system **900** includes an application server **930**, a database **940**, and a file system **950**, which may have the same or similar functionality as described above with respect to FIG. 8. Advantageously, in certain embodiments, the online learning system **900** conserves computing resources by enabling organizations to share components of the online learning system **900**.

The application server **930** in the depicted embodiment includes a provisioning module **932**, an instruction group authentication module **934**, a user authentication module **936**, and an online classroom module **938**. Fewer than or more than the depicted modules may be provided in other embodiments.

In certain embodiments, the provisioning module **932** can be a software component or the like that can group users into instruction groups. To assign users to instruction groups, the provisioning module **932** can assign or map an instruction group identifier to a set of users, such as all users in an organization. The instruction group identifier-user mappings can be stored in an instruction group-user table or tables **946** in the database **940**. The instruction group identifier can be kept internal to the online learning system **900** and may therefore be concealed or made inaccessible to users of the instruction groups. As a result, in certain embodiments the security of the data for each instruction group can be enhanced.

The provisioning module **932** might assign the same instruction group identifier to each user of an organization, so that all users in that organization are grouped together as one instruction group. Alternatively, the provisioning module **932** may assign different instruction group identifiers for different sub-groups of users within an organization. For example, users in different college classes might be assigned different instruction group identifiers, so that each class is considered a distinct instruction group. Instruction group identifiers may also be assigned hierarchically in certain implementations. One instruction group identifier might be assigned to an organization, for instance, and different instruction group identifiers might also be assigned to sub-groups within that organization. Many other combinations of instruction group identifier assignments can be used in various embodiments.

Additionally, users can be assigned multiple instruction group identifiers because users might belong to multiple instruction groups. For example, one instruction group identifier might be assigned to a user for each class the user is enrolled with. If a user is attending two schools, the user might be assigned an instruction group identifier for each school. Or, in the case of hierarchically-assigned instruction group identifiers described above, a user might have an instruction group identifier for the organization the user is affiliated with and another instruction group identifier for each class the user is taking with that organization.

In addition to assigning instruction group identifiers, the provisioning module **932** can assign one or more uniform resource indicators (URIs) to each instruction group. Each URI may include a string of characters that can be used to identify one or more network resources, such as instructional web pages or web sites, online classrooms, and the like. The network resources can allow users to access educational content, student, teacher, and course data, and the like. The URI can be, for example, a Uniform Resource Locator (URL) that identifies network resources using a hypertext transfer protocol (HTTP) or the like. Thus, each instruction group may be assigned access to different online classes and educational course content using the one or more URIs. The mappings of URIs to instruction groups may be stored in an instruction group-URI table or tables **948** in the database **940**.

The provisioning module **932** can also enable users to create user identification data, such as usernames and passwords, which users may use to log into the online learning system **900**. The user identification data may be associated with one or more instruction group identifiers and stored in the instruction group-user table **948** of the database **940**, or in a separate table.

Moreover, the provisioning module **932** can enable users to create or import educational content **952** into the file system **950**, which may include student, teacher, and course files and data. At least some of the educational content **952** can also be stored in the database **940** in certain embodiments. In addition, the provisioning module **932** can associate the educational content **952** with instruction group identifiers. Examples of associating educational content **952** with instruction group identifiers are described in further detail below with respect to FIG. 12 (educational content and user data stored in a database) and FIG. 13 (educational content and user data stored in a file system).

The instruction group authentication module **934** can be a software component or the like that can receive user requests to access educational content **952** in the file system **950** and/or in the database **940**. A user may send an access request by entering a URI into a web browser or other application on the user's computer system (see FIG. 8). The instruction group authentication module **934** may receive the access request over a communications medium, such as the communications medium **820** of FIG. 8. The instruction group authentication module **934** can obtain the URI entered by the user from the access request. Then, the instruction group authentication module **934** can use the URI to look up an instruction group identifier that corresponds to that URI in the instruction group-URI table **946**. Upon finding the instruction group identifier related to that URI, the instruction group authentication module **934** can pass the instruction group identifier to the user authentication module **936**.

The user authentication module **936** can be a software component or the like that can authenticate users prior to providing the users with access to the educational content **952** in the file system **950** and/or in the database **940**. The user authentication module **936** can obtain identification data from the user who provided the access request. The user identification data can include login data such as a username and password. Alternatively, the user identification data can include cookie data or the like that is persistently stored on the user's computer system. The user authentication module **936** can then determine if the user identification data corresponds to a valid user by accessing, for example, the instruction group-user table **948**. If the user identification data is stored in the database **940**, the user authentication module **936** can determine that the user is a valid user.

15

The user authentication module **936** can further determine which instruction group the user belongs to by accessing the instruction group identifier corresponding to that user in the instruction group-user table **948**. Then, the user authentication module **936** can compare the retrieved instruction group identifier to the instruction group identifier provided by the instruction group authentication module **936**. If the two instruction group identifiers match, then the user authentication module **936** can determine that the user is a valid member of an instruction group. Additionally, the user authentication module **936** can provide the user with access to the online classroom module **938** and educational content **952** of that instruction group.

The online classroom module **938** can be a software component or the like that can enable the user to access an online classroom or other educational programs. Using the online classroom or other educational programs, the user can access the educational content **952** corresponding to the user's instruction group stored in the file system **950** and/or in the database **940**.

Thus, in certain embodiments, by grouping users into instruction groups and associating educational content **952** with the instruction groups, the online learning system **900** can enable the database **940** and file system **950** to be shared by multiple groups of users. In addition, in certain embodiments the application server **930** can be shared by multiple groups of users, as is described in further detail with respect to FIG. **12** below.

FIG. **10** illustrates an embodiment of a process **1000** of provisioning users for accessing an online learning system. The process **1000** may be implemented in certain embodiments by any of the online learning systems described above, including the online learning systems **800** and **900**. More particularly, certain blocks of the process **1000** may be implemented by the provisioning module **932** described above with respect to FIG. **9**. The process **1000** in certain embodiments advantageously enables instruction groups to be created so as to facilitate secure sharing of computing resources in an online learning environment.

At block **1002**, a new instruction group is created. The new instruction may include one or more users such as students, teachers, administrators, combinations of the same and the like. The instruction group can be assigned an instruction group identifier which can be stored in a database or the like.

At block **1004**, one or more URIs are associated with the instruction group. The URIs can be associated further with one or more network resources such as online classrooms, web pages, and the like. In one implementation, the association of the uniform resource identifiers with instruction groups includes storing the instruction group identifiers together with the URIs in one or more tables of a database.

At block **1006**, student data and educational content can be created and/or imported into an online learning system. The student data and educational content can be stored in a file system and/or a database. At block **1008**, the student data and educational content can be associated with the instruction group by assigning or associating the instruction group identifier with the student data and educational content.

FIG. **11** illustrates an embodiment of a process **1100** for authenticating users to use an online learning system. The process **1100** may be implemented by any of the online learning systems described above, including the online learning systems **800** and **900**. In certain embodiments, the process **1100** can enable authentication of users of an online learning system in a manner that facilitates reduced computing resource consumption.

16

At block **1102**, a URI selected by a user can be received, for example, by the instruction group authentication module **934** described above. The URI can be selected by the user to identify one or more network resources, such as an online classroom, through which the user can access educational content and data. At block **1104**, the URI can be looked up in a database to find an instruction group that corresponds to the URI. This block **1104** may include obtaining an instruction group identifier that corresponds to the URI from the database. In an embodiment, block **1104** is also implemented by the instruction group authentication module **934**.

At block **1106**, identification information is received from the user. The identification information can include a username and password, persistently stored cookie data, combinations of the same, and the like. This block **1106** may be implemented, for example, by the user authentication module **936** described above.

It is determined at block **1108** whether the user identification information exists in the instruction group. Block **1108** may also be implemented by the user authentication module. Determining whether the user identification information exists for the identified instruction group can include accessing a table in the database to determine whether the user identification information exists in the database. If not, then the process **1100** proceeds to block **1110**.

If, however, the user identification is stored in the database, block **1108** can further include retrieving an instruction group identifier from the database that corresponds to the user. If so, the instruction group identifier corresponding to the user can be compared to the instruction group identifier for the URI found in block **1104** above. If the two instruction group identifiers match, then at block **1112**, the user is granted access to the educational content and data within the instruction group.

On the other hand, if the instruction group identifiers do not match, or if the user identification information is not valid (e.g., not in the database), the user is denied access to the educational content and data at block **1110**. In certain embodiments, the process **1100** may be repeated each time the user selects another URI to access additional educational content, user data, or the like. Advantageously, in some implementations, if at any time the user selects a URI that belongs to another instruction group (accidentally or otherwise), the instruction group identifier of the user's group will not match the instruction group identifier of the other group. As a result, the user will be denied access to that instruction group's URI. Thus, in certain embodiments, educational content and data for different instruction groups are kept separate from one another.

FIG. **12** illustrates an example database **1240** used that may be used with any of the online learning systems described above, such as the online learning systems **800** or **900**. The database **1240** may, for example, be used as the database **840** or **940**. The example database **1240** shown illustrates one possible implementation of associating instruction group identifiers with educational content, such as student, teacher, administrator, course, and other educational data.

Several example tables **1210** are shown, including tables **1210a**, **1210b**, and **1210c**. Each table **1210** has one or more rows of data **1222**. This data **1222** can include instruction group identifiers **1220**. Although not shown, the data **1222** might also include any of the data described above, such as student data, course data, teacher data, administrative data, combinations of the same, and the like. The data **1222** might also include educational content, such as documents, spreadsheets, images, drawings, audio, video, and the like. In addition, at least some of the data **1222**, while depicted in rows, may have other structures in various embodiments.

17

Within each table **1210**, the instruction group identifier **1220** is included in each row **1222**. Three different instruction group identifiers **1220** are shown, including `group_id1`, `group_id2`, and `group_id3`. Each instruction group identifier **1220** corresponds to one instruction group. Thus, in certain embodiments data **1222** appearing in a row with an instruction group identifier is associated with that instruction group.

As shown, different instruction group identifiers **1220** appear in each of the tables **1210**. Accordingly, data **1222** from different instruction groups are included in each of the tables **1210**. This need not be the case in certain embodiments; some tables **1210** may have data **1222** from fewer than all of the available instruction groups. However, by allowing the tables **1210** to include data from multiple instruction groups, the database **1240** in certain embodiments can be designed with one schema for multiple instruction groups. The database **1240** in certain embodiments can therefore be shared amongst instruction groups without duplicating tables. Because one common database schema is used, in certain embodiments one application server may be used to access the database **1240**.

FIG. **13** illustrates an example file system **1350** that may be used with any of the online learning systems described above, such as the online learning systems **800** or **900**. The file system **1350** may, for example, be used as the file system **850** or **950**. The example file system **1350** shown illustrates one possible implementation for associating instruction group identifiers with educational content, as well as student, teacher, administrator, and course files.

Blocks **1302** through **1308** of the example file system **1350** represent file folders, directories, or the like. The block **1302-1308** are arranged in a hierarchical structure with each block **1302-1308** as a node in the hierarchy. The highest node of the hierarchy in the depicted embodiment is the root folder, at block **1302**. Within the root folder are instruction group identifier folders at blocks **1304**. Two instruction group identifier folders are shown for illustrative purposes, namely `group_id1` (block **1304a**) and `group_id2` (block **1304b**). Each instruction group identifier folder corresponds to a different instruction group. In the depicted embodiment, the names of the instruction group identifier folders at blocks **1304** are instruction group identifiers. Thus, each instruction group identifier folder can contain files (including subfolders having files) for a particular instruction group corresponding to a particular instruction group identifier.

Within each instruction group identifier folder are course folders at blocks **1306**. Each course folder can represent a different course available to the given instruction group. Each course folder may include files for a course, such as online lessons, assessments, multimedia, teacher files, and the like. In addition, within certain of the course folders are student folders, at blocks **1308**. For conciseness, not all courses are shown with student folders. However, the other course folders may have student folders if students are enrolled in those courses. The student folders can contain student data, such as projects, homework, copies of assessments, and the like.

Two example file paths **1310** are shown, which can be used to access the files in the file system **1350**. The filenames include the names of folders in the hierarchy, including the instruction group identifier folder (e.g., “`group_id1`” or “`group_id2`”), a course folder (e.g., “`Course 1`” or “`Course 2`”), and a student folder (e.g., “`Student 1`”). In an embodiment, some or all of the files in the file system **1350** may be accessed directly by students, teachers, and/or administrators. In other embodiments, some or all of the files in the file system **1350** are accessed indirectly by students, teachers, and/or administrators using an application server, such as the

18

application server **830** or **930** described above. For example, a student might access course files from the file system **1350** indirectly through an online classroom, and the online classroom may programmatically access the files from the file system **1350** directly.

In alternative embodiments, the instruction group identifier folders **1304** may be at different levels in the file system **1350** hierarchy than that shown. Likewise, the course folders and student folders may be at different levels of the hierarchy, including on the same level. In addition, many other variations on the example file system **1350** depicted herein may be constructed.

TERMINOLOGY

Conditional language used herein, such as, among others, “can,” “could,” “might,” “may,” and the like, unless specifically stated otherwise, or otherwise understood within the context as used, is generally intended to convey that certain embodiments may include, while other embodiments may not include, certain features, elements and/or steps. Thus, such conditional language is not generally intended to imply that features, elements and/or steps are in any way required for one or more embodiments or that one or more embodiments necessarily include logic for deciding, with or without user input or prompting, whether these features, elements and/or steps are included or are to be performed in any particular embodiment.

Each of the processes, components, and algorithms described above may be embodied in, and fully automated by, code modules executed by one or more computers or computer processors. The code modules may be stored on any type of computer-readable medium or computer storage device. The processes and algorithms may also be implemented partially or wholly in application-specific circuitry. The results of the disclosed processes and process steps may be stored, persistently or otherwise, in any type of computer storage. In one embodiment, the code modules may advantageously be configured to execute on one or more processors, including sub-processors. In addition, the code modules may comprise, but are not limited to, any of the following: software or hardware components such as software object-oriented software components, class components and task components, processes methods, functions, attributes, procedures, subroutines, segments of program code, drivers, firmware, microcode, circuitry, data, databases, data structures, tables, arrays, variables, combinations of the same, and the like. In certain embodiments, certain processes or modules described herein may be distributed over multiple processors or computers, such as servers.

The various features and processes described above may be used independently of one another, or may be combined in various ways. All possible combinations and subcombinations are intended to fall within the scope of this disclosure. In addition, certain method or process steps may be omitted in some implementations.

While certain embodiments of the inventions disclosed herein have been described, these embodiments have been presented by way of example only, and are not intended to limit the scope of the inventions disclosed herein. Indeed, the novel methods and systems described herein may be embodied in a variety of other forms; furthermore, various omissions, substitutions and changes in the form of the methods and systems described herein may be made without departing from the spirit of the inventions disclosed herein. The accompanying claims and their equivalents are intended to cover

19

such forms or modifications as would fall within the scope and spirit of certain of the inventions disclosed herein.

What is claimed is:

1. An online learning system for providing online learning using an application service provider system, the online learning system comprising:

- a database comprising a plurality of instruction group identifiers and associated network resource identifiers, each of the instruction group identifiers corresponding to one of a plurality of instruction groups, each of the instruction groups comprising a plurality of student users, each of the network resource identifiers configured to identify one or more network resources, wherein the network resources comprise uniform resource locators (URLs);
- a file system comprising educational content for each of the instruction groups;
- an application server implemented in computer hardware and configured to be accessed by the plurality of instruction groups, the application server comprising:
 - a provisioning module configured to:
 - assign one of the instruction group identifiers and one or more of the network resource identifiers to each of the instruction groups, each of the instruction group identifiers uniquely identifying a selected one of the instruction groups while being hidden from each of the instruction groups to prevent user access to the instruction group identifiers, wherein the instruction group identifiers are hidden by being stored in the database so that they are not directly accessible to the student users; and
 - associate the instruction group identifiers with the educational content,
 - an instruction group authentication module configured to:
 - receive access requests from the student users from different ones of the instruction groups to access separate courses of the educational content stored in the file system, the access requests comprising different selected ones of the network resource identifiers from each of the instruction groups; and
 - retrieve, in response to each of the access requests, a selected one of the instruction group identifiers corresponding to the selected network resource identifier from the database,
 - such that for a selected one of the access requests from a selected one of the student users, the instruction group authentication module is configured to:
 - obtain a URL entered by the selected student user from the selected access request; and
 - use the URL to look up a first one of the instruction group identifiers that corresponds to the URL in a first table of the database, and
- a user authentication module configured to receive, with the access request, identification information from the selected student user, wherein the user authentication module is further configured to, in response to receiving the identification information from the selected student user and the first instruction group identifier from the instruction group authentication module:

20

- access a second table in the database to determine whether the identification information of the selected student user exists in the database,
- in response to determining that the identification information of the selected student user exists in the database, retrieve a second instruction group identifier from the database that corresponds to the selected student user, the second instruction group identifier corresponding to a selected one of the instruction groups,
- compare the first instruction group identifier provided by the instruction group authentication module to the second instruction group identifier corresponding to the selected student user,
- in response to determining that the first instruction group identifier matches the second instruction group identifier, granting the selected student user access to a selected one of the courses corresponding to the selected instruction group, and
- in response to determining that the first instruction group identifier does not match the second instruction group identifier, denying the selected student user access to the selected course, thereby preventing the selected student user from accessing those of the courses that are not associated with the selected instruction group of the selected student user; and
- an online classroom module configured to be executed by a computing system in a single computing instance in memory to provide each of the student users, including the selected student user, with simultaneous access to the educational content of the selected instruction group stored in the file system in response to receiving an indication from the user authentication module that the selected student user is a valid student user of the selected instruction group, without requiring multiple instances of the online classroom module to be executed, and wherein the use of the instruction group identifiers enables the database to have a single table schema for the plurality of instruction groups, thereby enabling the database to be shared by the plurality of instruction groups without duplicating tables for the plurality of instruction groups.

2. The system of claim 1, wherein the database comprises one or more tables comprising data from each of the instruction groups.

3. The system of claim 1, wherein the file system comprises a file hierarchy, wherein the educational content stored in the file hierarchy is configured to be accessed using a file path comprising the selected instruction group identifier.

4. The system of claim 1, wherein the plurality of instruction groups comprise a group of individuals within one or more of the following organizations: businesses, military, elementary schools, and secondary schools.

5. The system of claim 1, wherein each of the instruction groups comprise one or more teacher users.

6. The system of claim 1, further comprising a resource identifier table in the database, the resource identifier table associating each of the instruction group identifiers with one or more of the resource identifiers.
